

algorithm  $\rightarrow$  using stack

eg.1  $\text{nums1} = [4, 1, 2]$      $\text{nums2} = [2, 1, 3, 4]$

$\text{stack} = [ \quad ]$      $\text{res} = [-1, -1, -1]$

1. Check 1<sup>st</sup> value in  $\text{nums2}$

if its found in  $\text{nums1}$  using hashmap add it  
to the stack

$\text{stack} = [2, 1, ]$

2. when we get a value  $>$  top of stack. we pop it and add the value to the index of element we popped in the result.

(because we know that the elements in stack are all found in nums 1)

stack = [~~2~~, ~~3~~]

res = [-1, 3, 3]

stack = [4]

eg 2.       $\text{nums 1} = [4, 1, 2]$        $\text{nums 2} = [1, 3, 4, 2]$

$\text{stack} = []$        $\text{res} = [-1, -1, -1]$

1.       $\text{stack} = [1]$

2.       $\text{stack} = [\text{X}]$        $\text{res} = [-1, 3, -1]$

3.       $\text{stack} = [4, 2]$

eg 3 :       $\text{nums 1} = [2, 4]$        $\text{nums 2} = [1, 2, 3, 4]$

$\text{stack} = []$

$\text{res} = [-1, -1]$

1.  $\text{stack} = []$

2.  $\text{stack} = [2]$

3.  $\text{stack} = [\cancel{2}]$

4.  $\text{stack} = [4]$

$\text{res} = [3, -1]$

algorithm

loop through all elements of the superset.

if element is found in the subset else:  
add it to stack nothing

also compare current element to top of stack

if current element is bigger

get index of top of stack from subset

replace current element at the index in result

GG
